ABSTRACT

Because delayed gastric emptying and impaired gastric accommodation are regarded as pathophysiological mechanisms underlying functional dyspepsia (FD), prokinetics and fundic relaxants have been suggested as a new treatment for FD. We isolated tetrahydroberberine (THB), an isoquinoline alkaloid (5,8,13,13a-tetrahydro-9,10-dimethoxy-6H-benzo[g]-1,3-benzo[dioxolo][5,6-a]quinoline) from Corydalis tuber, and found that it has a micromolar affinity for dopamine D2 (pKi = 6.08) and 5-HT1A (pKi = 5.38) receptors but moderate to no affinity for other relevant serotonin receptors (i.e., 5-HT1B, 5-HT1D, 5-HT3, and 5-HT4; pKi < 5.00). Oral administration of THB not only resulted in significantly accelerated gastric emptying of normal rats in a bell-shaped relationship, with a maximal efficacy at a dose of 30 mg/kg, but also restored the delayed gastric emptying caused by apomorphine, which might be mediated by an antidopaminergic effect. Data from electromyography indicated enhanced motor function of the upper gastrointestinal tract by THB, which occurred through strengthening contractility and shortening the contraction interval. Furthermore, in rats stressed by repeated restraint, a significantly higher shift in the pressure-volume curve by THB (10 μg/kg, p < 0.05), which was inhibited by [O-methyl-3H]-N-[2-(4-(2-methoxyphenyl)-1-piperazinyl)ethyl]-N-(2-pyrindinyl)cyclohexanecarboxamide trihydrochloride (WAY-100635), a 5-HT1A antagonist, and N-nitro-L-arginine methyl ester, a nitric-oxide synthase inhibitor but not a vasoactive intestinal peptide antagonist, was observed. Oral administration of THB resulted in a drastic increase of gastric accommodation in Beagle dogs. Area under the volume versus time curve was increased significantly by THB (30 μg/kg, p < 0.01) and comparable with that of sumatriptan (3 mg/kg), a potent fundic relaxant. Taken together, our data suggested that THB, with D2 receptor antagonist and 5-HT1A receptor agonist properties, has significant potential as a therapeutic for treatment of FD.

Introduction

Functional dyspepsia (FD) is one of the main syndromes associated with gastrointestinal motor dysfunction (Tack, 2007). Delayed gastric emptying and impaired gastric accommodation are known to contribute to clinical manifestations, such as postprandial fullness, early satiation, epigastric pain, and burning sensation (Talley et al., 2006). Currently, prokinetics and fundic relaxants appear to be the drugs of choice for the treatment of FD (Tack, 2008; Brun and Kuo, 2010). Prokinetics stimulate smooth muscle contractions, leading to enhanced gastric emptying and acceleration of both small and large intestinal transit (Karamanolis and Tack, 2006; Tack, 2008). Fundic relaxants target impaired gastric accommodation of the upper gastrointestinal tract (Kindt and Tack, 2006; Tack, 2008). One of the major categories of prokinetic drugs is antidopaminergic agents (Tonini et al., 2004). The gastrointestinal tract actually has the ability to produce a substantial amount of dopamine. Enteric dopamine has been known to mediate inhibition of gut motility and decrease antroduodenal coordination in gut muscle, thereby inhibiting acetylcholine release from the cholinergic nerve by the activation of the neuronal dopamine D2 receptor.
to gastrointestinal motility are mediated by 5-HT₄ receptors and humans (Tsubouchi et al., 2003; Holtmann et al., 2006). Another significant category of prokinetic drugs is serotonergic agents (Tonini and Pace, 2006). The main effects relevant to gastrointestinal motility are mediated by 5-HT₄ receptors (De Maeyer et al., 2008). Tegaserod, an aminodiol compound, is a partial 5-HT₄ receptor agonist that has been shown to induce acceleration of gastric emptying in FD patients as well as healthy volunteers (Degen et al., 2001; Vakil et al., 2008). Cisapride is a nonselective 5-HT₃ receptor agonist with a partial weak 5-HT₃ antagonist effect that exhibits strong prokinetic actions (Mearin et al., 2004). However, tegaserod and cisapride were withdrawn due to the incidence of cardiovascular ischemia and serious cardiac arrhythmias, respectively (Wysowski et al., 2001; Pasricha, 2007). However, several serotonin receptors have been known to regulate gastric accommodation. Busiprone, a nonselective 5-HT₁A receptor agonist, has been involved in the gastric accommodation reflex by the release of nitric oxide (NO) (Coulie et al., 1999) in enteric neurons, resulting in muscle relaxation (Tack et al., 1999). In a clinical study, it was reported to be superior to the placebo control in lessening dyspeptic symptoms (Van Oudenhove et al., 2008). Subcutaneous administration of sumatriptan, a 5-HT₁B/D receptor agonist, was shown to restore meal-induced relaxation in patients with impaired gastric accommodation (Tack et al., 2000).

We previously reported on the strong gastroprokinetic effects of DA-9701, an herb-based novel prokinetic agent formulated with Pharbitis semen and Corydalis tuber (Lee et al., 2008). Administration of DA-9701 not only resulted in accelerated gastric emptying and gastrointestinal transit in normal rats as well as abnormally induced conditions but also induced an increase in gastric accommodation in Beagle dogs (Lee et al., 2008). In an effort to determine the active component(s), we performed binding assays for various receptors controlling gastrointestinal motor functions using several compounds isolated from DA-9701. Among them, tetrahydroberberine (THB), an isoquinoline alkaloid, 5,8,13,13α-tetrahydro-9,10-dimethoxy-6H-benzo[g]-1,3-benzodioxol-5,6-α-quinoline (Fig. 1), isolated from Corydalis tuber, was found to be bound to both dopamine D₂ and 5-HT₁A receptors but not other relevant serotonin receptors. In this study, we show that THB works not only as a prokinetic but also a fundic relaxant in animal models and that it has potential as a therapeutic for gastrointestinal motor dysfunctions such as FD.

**Materials and Methods**

**Identification of THB from Corydalis Tuber.** Tubers of *Corydalis yanhusuo* (10 kg) were extracted with 50% ethanol twice at room temperature. The ethanol extract (250 g) was suspended in distilled water (7.2 liters), followed by successive partitioning with n-hexane, trichloromethane, ethyl acetate, and n-butanol, yielding 10, 50, 4, and 26 g, respectively. The CHC₁₀ soluble fraction (28 g) was subjected to silica gel column chromatography (230–400 mesh, 600 g) and eluted with trichloromethane/methanol (15:1, 3.0 liters) and 5:1 (3.0 liters) to afford seven fractions [F₁, 15:1, 1.0 liter; F₂, 15:1, 1.0 liter; F₃, 15:1, 1.0 liter; F₄, 5:1, 0.5 liters; F₅, 5:1, 0.5 liters; F₆, 5:1, 1.0 liter; F₇, 5:1, 1.0 liter]. F₁ (3.5 g) and F₂ (10.0 g) were mixed and subjected to silica gel column chromatography (230–400 mesh, 250 g, n-hexane/ethyl acetate, 3:1) to give seven subfractions [SP₁–SP₇ (each 1.0 liter)]. SF₃ (350 mg) was purified by preparative high-performance liquid chromatography using a solvent of n-hexane/CHCl₃/ethyl acetate (6:3:5) at a flow rate of 2.0 ml/min [Apollo Silica 5-µm column; 250 × 10 mm; 5-µm particle size (Alltech, Nicholasville, KY); Shodex refractive index detector (Shodex, New York, NY)] to obtain THB (30 mg, tᵣ = 13.5 min).

**Chemicals.** N-Nitro-1-arginine methyl ester (L-NAME) hydrochlo-
ride, 1-arginine, [O-methyl-3H]-N-(2-(4-(2-methoxyphenyl)-1-piperazi-
nyl)ethyl]-N-(2-pyridyl)cyclohexane-carboxamide trihydrochloride (WAY-100635) maleate, and penicillin G were purchased from Sigma-Aldrich (St. Louis, MO). Tiletamine/zolazepam (Zoletil) was obtained from Virbac Laboratories (Carros, France). Ketamine was purchased from the Yuhwa Corporation (Seoul, South Korea). Vasopressin (VAP) antagonist (VIP) antagonist (COO-215/Kyan Kwan Sung Univ on January 24, 2012jpet.aspetjournals.org Downloaded from

* Buffer A, 50 mM Tris-HCl (pH 7.4), 10 mM MgSO_4, 0.5 mM EDTA, and 0.1% ascorbic acid; buffer B, 50 mM Tris-HCl (pH 7.4), 154 mM NaCl, 10 mM pargyline, and 30 mM isoprenaline; buffer C, 50 mM Tris-HCl (pH 7.5), 5 mM MgCl_2, and 1 mM EDTA; buffer D, 50 mM Tris-HCl (pH 7.4); buffer E, 50 mM Tris-HCl (pH 7.4), 120 mM NaCl, 5 mM KCl, 5 mM MgCl_2, and 1 mM EDTA.

International Ltd., Kent, UK previously soaked in 0.5% polyethyleneimine and a filter washed with ice-cold 50 mM Tris-HCl buffer (pH 7.4) at 25°C. Radioactivity was measured on a beta counter, the data were analyzed graphically with inhibition curves, and IC_{50} values were derived. K_i values were calculated according to the equation K_i = IC_{50}/(1 + C/(K_a)), with C as the concentration of each radioligand and K_a as the equilibrium dissociation constant of each radioligand. Binding assays for other serotonin (5-HT_1B and 5-HT_4) receptors were conducted at Ricerca Biosciences (Taipei, Taiwan) and Caliper Life Sciences (Hopkinton, MA).

Animals. Male Sprague-Dawley rats (200–220 g) were purchased from Orient Bio, Inc. (Gapyeung, South Korea) and had free access to water and a standard pellet diet. Before the experiments, rats were kept in an environmentally controlled room in groups of four. For restraint stress-induced impaired gastric compliance, rats were restrained in a plastic cage for 4 h per day for 4 days. Rats were fasted for 24 h before the start of the experiment (water was available ad libitum). At the beginning of the experiment, rats were sedated with a single dose of ketamine (50 mg/kg i.m.; Yanhan Corporation). Thereafter, a dose of 25 mg/kg was administered intramuscularly every hour to maintain sedation. During the experiment, the animals always were positioned lying down on their right sides. Ketamine sedation allowed the rats to tolerate swallowing of the finely folded polyethylene balloon that was adherent to the polyethylene tube and intubation of the tube during the experiment while spontaneous breathing was preserved. The bag was positioned in the stomach via a guide wire. A heating pad was used throughout the experiments to maintain the body temperature of the animal at 37°C. Gastric pressure–volume relationships were studied using a gastric barostat (Distender Series II; G&J Electronics, Toronto, ON, Canada). The system consists of an ultrathin polyethylene balloon (10-ml maximal capacity; Mui Scientific, Mississauga, ON, Canada), which was finely folded and can be inserted through the mouth into the proximal stomach, and has infinite compliance at the volumes used for distention of the rat stomach. A polyethylene balloon was adhered to a single lumen polyethylene tube (1.2-mm diameter; Natsume, Tokyo, Japan). The tube was connected to a pressure recording port and an air inflation port on a computer-driven barostat for recording of volume changes while the pressure was kept constant. Before the start of the experiment, the balloon was connected to the barostat, and the intrabag pressure was raised to 10 mm Hg. Monitoring of the constant intrabag volume ensured that there was no leak (Janssen et al., 2004). Drugs were administered after the intragastric volume maintained a stable baseline value during a period of at least 10 min at the constant pressure used. A single dose of THB was administered per experiment. Different doses (1, 3, 10, 30, or 100 μg/kg i.v.) of THB were divided randomly over different experiments. The doses of the drugs (WAY-100635, t-NAME, t-arginine, and VIP antagonist) used for mechanistic studies were chosen based on previous publications (Takahashi and Owyang, 1997; Zhou et al., 2008).

Canine Gastric Accommodation. Experiments were performed on four adult female Beagle dogs (7.9 kg b.w.t.). Dogs were trained to stand quietly in a sling without sedation. Experiments were performed on conscious dogs after allowing at least 15 days for recovery after surgery. Before each experimental session, the dogs were fasted for at least 18 h; water was available ad libitum. Between consecutive experimental sessions with the same animal, a washout period...
of at least 72 h was allowed. Dogs were observed throughout the experiment, and any sign of discomfort or anomalous behavior was noted. The gastric cannula was opened, and after verification that the stomach did not contain any food residues, the bag of the barostat was introduced into the proximal stomach (position of the bag checked radiographically). Before and at the end of the in vivo tests, the bag was checked for air leaks by increasing the pressure to 20 mm Hg (Chen et al., 2009). To determine the influence of 5-HT_{1A} receptor antagonists in the mediation of canine gastric accommodation induced by THB, WAY-100635 (0.1 mg/kg) was tested versus 30 

### Results

**Identification and Characterization of THB.** In an effort to determine the active component(s) from DA-9701, we have fractionated the ethanol extract of Corydalis tuber according to polarity and purified several compounds by column chromatography, as described under Materials and Methods. We have screened and chased the affinities of the compounds for relevant receptors involved in the control of gastrointestinal motor function, which included various serotonin receptors and dopamine D_{2} receptor, by radioligand competition binding assays, according to the conditions presented in Table 1. We found that a compound named SF-2 has micromolar affinities for dopamine D_{2} receptor (pK_{i} = 6.08) and 5-HT_{1A} receptor (pK_{i} = 5.38) but moderate to no affinity for other relevant serotonin receptors (i.e., 5-HT_{1B}, 5-HT_{3D}, 5-HT_{4}; pK_{i} < 5.00), as presented in Table 2. SF-2 showed a similar affinity for D_{2} receptor to that of itopride (in this study) and a 1434-fold lower affinity than that of domperidone compared with values reported previously (Freedman et al., 1994). In terms of 5-HT_{1A} receptor affinity, SF-2 showed 132 times lower affinity than that of cisapride (Lee et al., 1999). In an effort to determine active component(s) from DA-9701, we have fractionated the ethanol extract of Corydalis tuber according to polarity and purified several compounds by column chromatography, as described under Materials and Methods. We have screened and chased the affinities of the compounds for relevant receptors involved in the control of gastrointestinal motor function, which included various serotonin receptors and dopamine D_{2} receptor, by radioligand competition binding assays, according to the conditions presented in Table 1. We found that a compound named SF-2 has micromolar affinities for dopamine D_{2} receptor (pK_{i} = 6.08) and 5-HT_{1A} receptor (pK_{i} = 5.38) but moderate to no affinity for other relevant serotonin receptors (i.e., 5-HT_{1B}, 5-HT_{3D}, 5-HT_{4}; pK_{i} < 5.00), as presented in Table 2. SF-2 showed a similar affinity for D_{2} receptor to that of itopride (in this study) and a 1434-fold lower affinity than that of domperidone compared with values reported previously (Freedman et al., 1994). In terms of 5-HT_{1A} receptor affinity, SF-2 showed 132 times lower affinity than that of cisapride (Lee et al., 1999).

**Data Analysis.** Results were expressed as mean ± S.E.M. Differences in the data were evaluated using paired t test for the comparison of two groups or one-way analysis of variance (ANOVA) followed by Dunnett’s test for multiple comparisons. A difference was considered significant if p < 0.05.

**Effects of THB on Gastric Emptying.** To estimate the prokinetic effects of THB, we performed gastric emptying experiments using semisolid meals. In normal rats, compared with the control group, THB induced significant acceleration of gastric emptying. As shown in Fig. 2A, data from the control group indicated that only 28.1 ± 1.1% was emptied; however, the decrease in residual meal by THB was significant. The effect was a bell-shaped relationship, with a maximal efficacy at the dose of 30 μg/kg. The residual percentage of the meal was 50.3 ± 2.3% (p < 0.05) and the maximal effect of THB was comparable with that achieved with cisapride at a dose of 10 mg/kg p.o. (54.8 ± 1.5, n = 8, p < 0.05). We next used delayed models of gastric emptying to determine whether THB, known to function as a D_{2} receptor antagonist (Wu and Jin, 1996, 1997), is capable of correcting abnormally depressed gastric emptying. Apomorphine has inhibitory effects on gastric emptying through its action as a dopamine agonist (Blancquaert et al., 1982). Administration of apomorphine (0.05 mg/kg s.c.) resulted in a marked delay of gastric emptying of a semisolid meal by approximately 50% compared with that of naive rats (37.8 ± 2.4 versus 68.9 ± 7.4). Delayed gastric emptying was restored by THB. At doses of 10 and 100 μg/kg, the gastric emptying rates were 48.8 ± 5.2 (p < 0.05) and 55.9 ± 3.7 (p < 0.01, respectively). The effect of 100 μg/kg THB was comparable with that of itopride at a dose of 30 mg/kg (Fig. 2B). These results suggested that THB could induce acceleration of gastric emptying under normal conditions as well as apomorphine-induced abnormally delayed gastric emptying.

Effects of THB on Motor Activity in the Upper Gastrointestinal Tract. To further evaluate the question of whether THB enhances gastric motor function, we measured contractility using EMG. Rats received surgical implantation with 41 pairs of electrodes in the antrum, duodenum, and jejunum. The effects of THB on gastrointestinal contractile activity upon intravenous injection under fasting conditions are presented in Fig. 3. Control rats injected with saline showed a typical pattern of motor activity; however, injection of THB (10 μg/kg i.v.) resulted in significant enhancement of contractile force in the gastrointestinal tract, and an overall increase in the motor activity index was observed. As shown in Fig. 3A, peak count was increased significantly by THB, not only in the gastric antrum but also the duodenum and jejunum, compared with that of the control. Amplitude and integral areas showed a significant increase, as shown in Fig. 3, B and C, respectively, indicating that THB induced stronger contractility compared with that of the control. The effects were prominent in the jejunum, resulting in approximately 2-fold increases, compared with that of the control. Furthermore, the interval of MMC was measured from the end of one activity to the end of the next one. The MMC occurred at regular intervals of approximately 10.1 ± 1.3 min in the control group. Injections of THB resulted in significant shortening of the interval between the MMCs in the duodenum (7.3 ± 1.1 min, p < 0.05) and jejunum (7.4 ± 0.4 min, p < 0.01), although significant effects were not observed in the antrum (Fig. 3D). These results suggested that THB could enhance gastric motor function in the upper gastrointestinal tract through strengthening contractility and shortening the contraction interval.

Fundic Relaxing Effects of THB. Because DA-9701 not only enhanced gastric accommodation in Beagle dogs, we also determined the binding affinity of THB to the 5HT1A receptor (Table 2) and attempted to determine whether THB has the ability to perform fundic relaxant activities, using two animal models. We first used rats with impaired gastric compliance by repeated restraint stress. Rats were restrained in small plastic bags for 4 h per day for 4 consecutive days; balloons connected with a barostat then were inserted into the stomach for the measurement of the volume-pressure relationship. A significant shift (p < 0.05) of the pressure-volume curve was observed in stressed rats toward the lower volume compared with that of control rats, indicating im-

**Fig. 2.** Effects of THB on gastric emptying. A, in normal rats, after 24 h of fasting, animals (n = 8 for each group) were orally administered THB and cisapride (Cisa) at the indicated doses or 3% hydroxypropyl methylcellulose as a vehicle (Con). B, effects of THB on delayed gastric emptying. In an apomorphine-induced delay model, animals were orally administered THB and itopride (Ito) at the indicated doses or 3% hydroxypropyl methylcellulose as a vehicle (Con) and were injected simultaneously with apomorphine (0.05 mg/kg s.c.). Naive animals were not injected with apomorphine and were orally administered the vehicle. Percentage gastric emptying was calculated as described under Materials and Methods. *, p < 0.05; **, p < 0.01 versus control; †, p < 0.01 versus normal (one-way ANOVA with post hoc Dunnett’s test).

**Fig. 3.** Effects of THB on gastrointestinal motor activity in conscious rats. THB (10 μg/kg i.v.) versus control (intravenous saline) on the different EMG parameters (A, peak count; B, amplitude; C, integral area; D, interval of MMC) from the rat gastric antrum at 5 mm proximal to the pylorus, the duodenum, and the jejunum, respectively, at 5 and 15 cm distal to the pylorus. *, p < 0.05; **, p < 0.01 versus control (one-way ANOVA with post hoc Dunnett’s test).
paired gastric compliance, resulting in a significantly lower maximal gastric volume (data not shown). Intravenous administration of THB after maintenance of the intragastric volume at a stable baseline value resulted in a significantly higher shift in the pressure–volume curve in rats treated with the doses of 10 μg/kg (Fig. 4C) and 30 μg/kg (Fig. 4D), whereas doses below 10 and 100 μg/kg showed no significant effects. At \( \frac{1}{2} P_{\text{max}} \), the gastric volume was 9.6 ± 0.8 ml (rats treated with a dose of 10 μg/kg, \( p < 0.05 \)) versus 7.6 ± 0.8 ml (control), and in rats treated with a dose of 30 μg/kg, the value was 9.5 ± 1.0 ml (\( p < 0.05 \)) versus 6.8 ± 0.9 ml (control). The maximum delta volume (approximately 2 ml) at \( \frac{1}{2} P_{\text{max}} \) was obtained in rats treated with 10 μg/kg THB (Fig. 4F). In addition, in an effort to understand the mode of action for gastric relaxation, we conducted an antagonist study. WAY-100635, a 5HT1A receptor antagonist, was chosen based on data from the receptor binding assay of THB to the 5HT1A receptor, and, additionally, other antagonists of signaling molecules, including NO and VIP, also were used (Desai et al., 1991). WAY-100635 was administered (0.1 mg/kg i.v.) 10 min before the administration of THB (10 or 30 μg/kg i.v.) at doses presenting significant efficacy. THB induced an increase of gastric volume that was inhibited significantly by WAY-100635. The delta volume at \( \frac{1}{2} P_{\text{max}} \) was lowered to 0.02 ml (Fig. 5). Administration of L-NAME (10 mg/kg), a NO synthase inhibitor, also resulted in significant inhibition of delta volume at \( \frac{1}{2} P_{\text{max}} \) (0.2 ± 0.1 versus 1.5 ± 0.3 ml, \( p < 0.05 \)). In addition, to exclude nonspecific effects of L-NAME, we used l-arginine, a NO precursor. When l-arginine (100 μM/kg) was administered, L-NAME restored the gastric volume to the levels induced by THB, indicating involvement of NO. However, administration of the VIP antagonist (30 nmol/kg) did not result in any changes in gastric volume induced by THB. As shown in Fig. 5, the delta volume at \( \frac{1}{2} P_{\text{max}} \) was 1.0 ± 0.3 ml. We then assessed the effects of THB on gastric accommodation by oral administration in Beagle dogs surgically implanted with a barostat. Postprandial gastric volume was evaluated in three time intervals, 10 to 35, 35 to 60, and 10 to 60 min, after each meal (Fig. 6A). In dogs who received 30 μg/kg THB, postprandial volume was significantly higher than that of the control for each time interval (\( p < 0.01 \)), which was comparable with those of sumatriptan (3 mg/kg i.v.), a potent fundic relaxant. Area under the volume versus time curve was increased significantly in dogs treated with THB (Fig. 6B). Taken together, these data suggested the potential of THB as a fundic relaxant for an increase of gastric accommodation.

**Discussion**

This study began from DA-9701, an herb-based gastroprokinetic agent formulated with Pharthis semen and Corydalis tuber (Lee et al., 2008). A phase III clinical trial of DA-9701 for FD has been completed recently, and we are anticipating DA-9701 as a novel natural medicine for treatment of FD in South Korea. In this study, we provided several pieces of evidence to show that THB, an isoquinoline alkaloid isolated from Corydalis tuber, is one of the active component(s) responsible for gastroprokinetic and fundic relaxing activity. THB has been known as an antidopaminergic agent; however, for the first time, we recognized THB as an agonist for the 5-HT1A receptor and explored the possibility of its possible use for the treatment of FD. We demonstrated that THB stimulates gastric emptying and gastrointestinal contractility as well as enhances gastric accommodation in conscious animals, which might be mediated by dopamine D2 and/or serotonin 5-HT1A receptors. These findings suggested that THB may have potential as a novel agent in the treatment of FD associated with gastric motor dysfunction.
The maximal effective dose was 30 mg/kg and metoclopramide at a dose of 10 mg/kg were comparable with those of su-matripan (3 mg/kg). On the basis of our data, THB is an orally available as well as injectable fundic relaxant acting to jejunum. Taken together, THB appears to be a new antidopaminergic prokinetic.

Both intravenous injection and oral administration of THB resulted in significantly increased gastric accommodation in restraint-stressed rats and conscious dogs, respectively. It has been accepted currently that fundic relaxation can be achieved by agonists for 5-HT1A receptor subtypes, including the 5-HT1A and/or 5-HT1B/D receptors. Activation of the 5-HT1A receptor causes a release of NO for the relaxation of the gastric fundus and a decrease of gastric fundus tone (Desai et al., 1991; Coulie et al., 1999). Sumatriptan, a 5-HT1B/D receptor agonist, has been reported to induce fast and profound relaxation of the proximal stomach in both canine models and human studies (Tack et al., 2000); however, its cost and mode of administration appear to be unsuitable for chronic treatment of FD. The nonslective 5-HT1A receptor agonist buspirone reduces fundic tone, enhances meal-induced relaxation, and enhances gastric accommodation and gastric emptying in humans in a dose-dependent manner; however, due to its central side effects, it is not suitable for routine clinical use for the treatment of FD (Koizumi et al., 1992). THB not only binds the 5-HT1A receptor but also induces a significant increase of gastric volume (at a dose of 10 μg/kg) in rats stressed by restraint. The relaxing effects were blocked almost completely by WAY-100635, a 5-HT1A receptor antagonist, and we also observed that treatment with a NO synthase inhibitor resulted in significant suppression of the THB-induced increase in gastric volume, which was reversed by the NO donor, whereas the VIP antagonist was not able to affect the gastric volume increase by THB. In addition, we recognized that oral administration of THB resulted in significantly increased postprandial gastric volume in conscious dogs and that the effects at a dose of 30 μg/kg were comparable with those of sumatripan (3 mg/kg). On the basis of our data, THB is an orally available as well as injectable fundic relaxant acting on the 5-HT1A receptor. For safety, we performed testing to determine whether THB can induce ataxia, a serious side effect of the 5-HT1A receptor agonist, using the rotarod assay (Millan et al., 1996). THB (0.3 mg/kg, i.v.) did not show any rotarod performance 30 min after the administration, whereas buspirone (3 mg/kg i.v.) produced a significant decrease in rotarod performance (data not shown). Taken together, our study suggested that THB has significant potential as a therapeutic for FD for the enhancement of gastric motor function. Although the question of whether and/or how dual activities on dopamine and serotonin by THB work synergically or co-operatively on gastric emptying and gastric accommodation remains to be elucidated, considering the superior effects of THB to the conventional drugs and its safety, further research for its development as medicine clearly is needed.
Authorship Contributions

Participated in research design: T.H. Lee, Son, and Jin.
Conducted experiments: Kim and S.O. Lee.
Performed data analysis: K.K. Lee and Jin.
Wrote or contributed to the writing of the manuscript: Jin.
